

ABSTRACT

An access communication system provides access between a user system and a plurality of communication networks. The plurality of communication networks provide services to a user in the user system. An access communication system includes a database system and an access server that is connected to the user system and the plurality of communication networks. The access server transfers information identifying a billing code for the user from the user system to the database system. Two examples of billing codes are prepaid account codes and bank card numbers. The database system receives the information identifying the billing code for the user. The database system then processes the billing code to determine if the user is allowed to use the access communication system. The database system provides access to the access communication system in response to the determination that the user is allowed to use the access communication system.
